

Algebra und Dynamik von Quantensystemen Blatt Nr. 1

Jun Wei Tan*

Julius-Maximilians-Universität Würzburg

(Dated: October 19, 2025)

Problem 1 (CCRs vs. Boundedness). Consider two bounded operators A and B on a Hilbert space \mathcal{H} , i.e.

$$\exists a \in \mathbb{R} : \forall \psi \in \mathcal{H} : \|A\psi\| \leq a\|\psi\|, \quad (1a)$$

$$\exists b \in \mathbb{R} : \forall \psi \in \mathcal{H} : \|B\psi\| \leq b\|\psi\|. \quad (1b)$$

Show that the canonical commutation relations

$$[A, B] = AB - BA = i \quad (2)$$

are inconsistent with the assumption of boundedness for the operators A and B .

NB: It is not necessary to find an original proof. It suffices to find, understand and present a proof from the literature.

Proof. The proof comes from rudin: Let A be a normed algebra, and $x, y \in A$. We assume that

$$xy - yx = 1$$

The first step is to prove that $xy^n - y^n x = ny^{n-1}$ for all $n \in \mathbb{N}$. This is true for $n = 1$. Then, by induction, if

$$xy^n - y^n x = ny^{n-1},$$

it follows that

$$\begin{aligned} xy^{n+1} - y^{n+1}x &= (xy^n - y^n x)y + y^n(xy - yx) \\ &= ny^n + y^n \\ &= (n+1)y^n \end{aligned}$$

* jun-wei.tan@stud-mail.uni-wuerzburg.de

Additionally, we note that $y^n \neq 0$ for all n . Otherwise, we would choose the minimum n , and get

$$0 = xy^n - y^n x = ny^{n-1},$$

a contradiction to the minimality of n . Now, we have

$$n\|y^{n-1}\| = \|xy^n - y^n x\| \leq 2\|x\|\|y\|\|y\|^{n-1}$$

and

$$2\|x\|\|y\| \geq n,$$

a contradiction. □

Problem 2 (Classical Dynamics on the 2-Torus). Consider a classical dynamical system with the 2-Torus $T^2 = S^1 \times S^1$ as phase space Γ (this is not a cotangent bundle, but it has the technical advantage of being compact).

Using standard coordinates $(\theta_1, \theta_2) \in [0, 2\pi)^2$, a consistent Poisson bracket is given by

$$\{f, g\} = \frac{\partial f}{\partial \theta_1} \frac{\partial g}{\partial \theta_2} - \frac{\partial f}{\partial \theta_2} \frac{\partial g}{\partial \theta_1}. \quad (3)$$

Assume that the Hamiltonian is

$$\begin{aligned} H : \Gamma &\rightarrow \mathbb{R} \\ (\theta_1, \theta_2) &\mapsto H(\theta_1, \theta_2) = c \cos \theta_1. \end{aligned} \quad (4)$$

In order to be well defined globally, the Hamiltonian must be periodic in θ_1 and θ_2 . This is the simplest choice.

1. Derive the equations of motion.
2. Determine the flow Φ of a phase space point $(\theta_1, \theta_2) \in \Gamma$.
3. Determine the time evolution of the state ω , where

$$\omega(f) = \int_{\Gamma} d^2\theta f(\theta) \omega(\theta) \quad (5)$$

with

$$\begin{aligned} \omega : \Gamma &\rightarrow \mathbb{R} \\ (\theta_1, \theta_2) &\mapsto \omega(\theta_1, \theta_2) = \frac{1}{\pi^2} \sin^2 \theta_1 \sin^2 \theta_2. \end{aligned} \quad (6)$$

HAMILTONIAN DYNAMICS

The Hamiltonian is a function on the phase space

$$H = H(q_1, \dots, q_n, p_1, \dots, p_n).$$

The flow solves the canonical equations of motion

$$\begin{aligned}\frac{dq_i}{dt} &= \frac{\partial H}{\partial p_i} \\ \frac{dp_i}{dt} &= -\frac{\partial H}{\partial q_i}\end{aligned}$$

We can also define the Poisson bracket

$$\{f, g\} = \sum_i \left(\frac{\partial f}{\partial q_i} \frac{\partial g}{\partial p_i} - \frac{\partial f}{\partial p_i} \frac{\partial g}{\partial q_i} \right)$$

It is immediately clear that the Poisson bracket is antisymmetric; additionally, we have the canonical commutation relations

$$\{q, p\} = 1, \{q, q\} = \{p, p\} = 0$$

Clearly, because $\frac{\partial q}{\partial p} = \frac{\partial p}{\partial q} = 0$, we can rewrite the canonical commutation relations as

$$\begin{aligned}\frac{dq_i}{dt} &= \{q_i, H\} \\ \frac{dp_i}{dt} &= \{p_i, H\}\end{aligned}$$

STATES AS FUNCTIONALS

Proof. 1. The equations of motion are

$$\frac{d\theta_1}{dt} = \frac{\partial H}{\partial \theta_2} = 0$$

and

$$\frac{d\theta_2}{dt} = -\frac{\partial H}{\partial \theta_1} = c \sin \theta_1$$

2. Clearly, the first equation tells us that θ_1 is a constant; since the right hand side of

equation 2 is now a constant, θ_2 varies linearly with time.

$$\Phi^t \begin{pmatrix} \theta_1 \\ \theta_2 \end{pmatrix} = \begin{pmatrix} \theta_1 \\ \theta_2 + ct \cos \theta_1 \end{pmatrix}$$

□

Problem 3 (Classical Dynamics on the 2-Sphere). Consider a classical dynamical system with the 2-Sphere S^2 as phase space Γ (this is again not a cotangent bundle, but the technical advantage of being compact and is highly symmetric).

Using standard spherical coordinates $(\theta, \phi) \in [0, \pi] \times [0, 2\pi)$, a consistent Poisson bracket is given by

$$\{f, g\} = \frac{1}{\sin \theta} \left(\frac{\partial f}{\partial \theta} \frac{\partial g}{\partial \phi} - \frac{\partial f}{\partial \phi} \frac{\partial g}{\partial \theta} \right). \quad (7)$$

Assume that the Hamiltonian is

$$\begin{aligned} H : \Gamma &\rightarrow \mathbb{R} \\ (\phi, \theta) &\mapsto H(\phi, \theta) = \cos \theta. \end{aligned} \quad (8)$$

In order to be well defined globally, the Hamiltonian must be periodic in θ and ϕ . This is one of the simplest choices.

1. Show that the Poisson bracket satisfies all requirements.
2. Determine the flow Φ of a phase space point $(\theta, \phi) \in \Gamma$.
3. Determine the time evolution of the state ω , where

$$\omega(f) = \int_{\Gamma} \sin \theta \, d\theta \, d\phi \, f(\theta, \phi) \, \omega(\theta, \phi) \quad (9)$$

with

$$\begin{aligned} \omega : \Gamma &\rightarrow \mathbb{R} \\ (\theta, \phi) &\mapsto \omega(\theta, \phi) = \frac{2}{\pi^2} \sin \theta \cos^2 \phi. \end{aligned} \quad (10)$$
